ESTIMATING THE TENSOR OF CURVATURE OF A SURFACE FROM A POLYHEDRAL APPROXIMATION

Gabriel Taubin

ICCV 1995

IBM T.J.Watson Research Center
P.O.Box 704, Yorktown Heights, NY 10598
taubin@watson.ibm.com

Abstract

Estimating principal curvatures and principal directions of a surface from a polyhedral approximation with a large number of small faces, such as those produced by iso-surface construction algorithms, has become a basic step in many computer vision algorithms. Particularly in those targeted at medical applications. In this paper we describe a method to estimate the tensor of curvature of a surface at the vertices of a polyhedral approximation. Principal curvatures and principal directions are obtained by computing in closed form the eigenvalues and eigenvectors of certain 3×3 symmetric matrices defined by integral formulas, and closely related to the matrix representation of the ten-

mate principal curvatures at the vertices of a triangulated surface. Both this algorithm and ours are based on constructing a quadratic form at each vertex of the polyhedral surface and then computing eigenvalues (and eigenvectors) of the resulting form, but the quadratic forms are different. In our algorithm the quadratic form associated with a vertex is expressed as an integral, and is constructed in time proportional to the number of neighboring vertices. In the algorithm of Chen and Schmitt, it is the least-squares solution of an overdetermined linear system, and the complexity of constructing it is quadratic in the number of neighbors.

2 The Tensor of Curvature

Taubin Matrix

$$M := \frac{1}{2\pi} \int_{-\pi}^{\pi} \kappa_{\theta} T_{\theta} T_{\theta}^{\top} d\theta$$

$$\kappa_{\theta} := \kappa_1 \cos^2 \theta + \kappa_2 \sin^2 \theta$$

$$T_{\theta} := T_1 \cos \theta + T_2 \sin \theta$$

Taubin Matrix

$$M := \frac{1}{2\pi} \int_{-\pi}^{\pi} \kappa_{\theta} T_{\theta} T_{\theta}^{\top} d\theta$$

- Eigenvectors are N , T_1 , and T_2
- Eigenvalues are $\frac{3}{8}\kappa_1 + \frac{1}{8}\kappa_2$ and $\frac{1}{8}\kappa_1 + \frac{3}{8}\kappa_2$

Taubin's Approximation

$$M := \frac{1}{2\pi} \int_{-\pi}^{\pi} \kappa_{\theta} T_{\theta} T_{\theta}^{\top} d\theta$$

$$\tilde{M}_{v_i} := \sum_{v_j \sim v_i} w_{ij} \kappa_{ij} T_{ij} T_{ij}^{\top}$$

Taubin's Approximation

Divided difference approximation

$$\tilde{M}_{v_i} := \sum_{v_j \sim v_i} w_{ij} \kappa_{ij} T_{ij} T_{ij}^\top$$

Estimating Curvatures and Their Derivatives on Triangle Meshes

Szymon Rusinkiewicz
Princeton University

3DPVT '04

Abstract

The computation of curvature and other differential properties of surfaces is essential for many techniques in analysis and rendering. We present a finite-differences approach for estimating curvatures on irregular triangle meshes that may be thought of as an extension of a common method for estimating per-vertex normals. The technique is efficient in space and time, and results in significantly fewer outlier estimates while more broadly offering accuracy comparable to existing methods. It generalizes naturally to computing derivatives of curvature and higher-order surface differentials.

1 Introduction

As the acquisition and use of sampled 3D geometry become more widespread, 3D models are increasingly becoming the focus of analysis and signal processing techniques previously applied to data types such as audio, images, and video. A key component of algorithms such as feature detection, filtering, and indexing, when applied to both geometry and other data types, is the discrete estimation of differential quantities. In

Figure 1: Left: suggestive contours for line drawings [DeCarlo et al. 2003] are a recent example of a driving application for the estimation of curvatures and derivatives of curvature. Right: suggestive contours are drawn along the zeros of curvature in the view direction, shown here in blue, but only where the derivative of curvature in the view direction is positive (the curvature derivative zeros are shown here in red). This paper describes a general

Second Fundamental Form Matrix

$$\begin{aligned} II &:= \begin{pmatrix} D_u N & D_v N \end{pmatrix} \\ &= \begin{pmatrix} \frac{\partial N}{\partial u} \cdot \vec{u} & \frac{\partial N}{\partial v} \cdot \vec{u} \\ \frac{\partial N}{\partial u} \cdot \vec{v} & \frac{\partial N}{\partial v} \cdot \vec{v} \end{pmatrix} \end{aligned}$$

Assume u, v are orthogonal

Second Fundamental Form Matrix

$$\vec{s} = c_1 \vec{u} + c_2 \vec{v}$$
$$\implies II \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = D_{\vec{s}} N$$

Finite Difference Per-Face

$$\mathbf{II} \begin{pmatrix} e_0 \cdot u \\ e_0 \cdot v \end{pmatrix} = \begin{pmatrix} (n_2 - n_1) \cdot u \\ (n_2 - n_1) \cdot v \end{pmatrix}$$

$$\mathbf{II} \begin{pmatrix} e_1 \cdot u \\ e_1 \cdot v \end{pmatrix} = \begin{pmatrix} (n_0 - n_2) \cdot u \\ (n_0 - n_2) \cdot v \end{pmatrix}$$

$$\mathbf{II} \begin{pmatrix} e_2 \cdot u \\ e_2 \cdot v \end{pmatrix} = \begin{pmatrix} (n_1 - n_0) \cdot u \\ (n_1 - n_0) \cdot v \end{pmatrix}$$

Consistent Computation of First- and Second-Order Differential Quantities for Surface Meshes

Xiangmin Jiao*

College of Computing
Georgia Institute of Technology

Abstract

Differential quantities, including normals, curvatures, principal directions, and associated matrices, play a fundamental role in geometric processing and physics-based modeling. Computing these differential quantities *consistently* on surface meshes is important and challenging, and some existing methods often produce inconsistent results and require *ad hoc* fixes. In this paper, we show that the computation of the gradient and Hessian of a height function provides the foundation for consistently computing the differential quantities. We derive simple, *explicit* formulas for the transformations between the first- and second-order differential quantities (i.e., normal vector and curvature matrix) of a smooth surface and the first- and second-order derivatives (i.e., gradient and Hessian) of its corresponding height function. We then investigate a general, flexible numerical framework to estimate the derivatives of the height function based on local polynomial fittings formulated as weighted least squares approximations. We also propose an iterative fitting

often require *ad hoc* fixes to avoid crashing of the code, and their effects on the accuracy of the applications are difficult to analyze.

The ultimate goal of this work is to investigate a mathematically sound framework that can compute the differential quantities *consistently* (i.e., satisfying the intrinsic constraints) with provable *convergence* on general surface meshes, while being flexible and easy to implement. This is undoubtedly an ambitious goal. Although we may have not fully achieved the goal, we make some contributions toward it. First, using the singular value decomposition [Golub and Van Loan 1996] of the Jacobian matrix, we derive explicit formulas for the transformations between the first- and second-order differential quantities of a smooth surface (i.e., normal vector and curvature matrix) and the first- and second-order derivatives of its corresponding height function (i.e., gradient and Hessian). We also give the explicit formulas for the transformations of the gradient and Hessian under a rotation of the coordinate system. These transformations can be obtained without forming the shape operator and the associated computation of its eigenvalues or eigenvectors. We

Visualization and Math. III

Summary. This paper proposes a unified and consistent set of flexible tools to approximate important geometric attributes, including normal vectors and curvatures on arbitrary triangle meshes. We present a consistent derivation of these first and second order differential properties using *averaging Voronoi cells* and the mixed Finite-Element/Finite-Volume method, and compare them to existing formulations. Building upon previous work in discrete geometry, these operators are closely related to the continuous case, guaranteeing an appropriate extension from the continuous to the discrete setting: they respect most intrinsic properties of the continuous differential operators. We show that these estimates are optimal in accuracy under mild smoothness conditions, and demonstrate their numerical quality. We also present applications of these operators, such as mesh smoothing, enhancement, and quality checking, and show results of denoising in higher dimensions, such as for tensor images.

Abstract

A robust statistics approach to curvature estimation on discretely sampled point clouds, is presented. The method exhibits accuracy, stability and sampled surfaces with irregular configurations. Within an M-estimation noise and structured outliers by sampling normal variations in an ad each point. The algorithm can be used to reliably derive higher order d surface normals while preserving the fine features of the normal and with state-of-the-art curvature estimation methods and shown to improv across ground truth test surfaces under varying tessellation densities noise. Finally, the benefits of a robust statistical estimation of curvature applications of mesh segmentation and suggestive contour rendering.
